

ABSTRACT OF THE DISCLOSURE

A generator generates a composite code from dithered copies of a reference
code to form an optimal stationary dither code. The generator either dithers the length
of the reference code to generate a boundary dither code composed of a series varying
length short codes, or it dithers the phase of the reference code to generate rotation
dither code composed of a series of fixed length short codes that vary in phase. The
generator dithers the reference code according to a dither pattern. The composite code
is an optimal dither code, having an optimal autocorrelation properties, by generating
a dither pattern in which phase vectors for the constituent code are not repeated within
the code
